

CAMPLET:

Seasonal adjustment without revisions

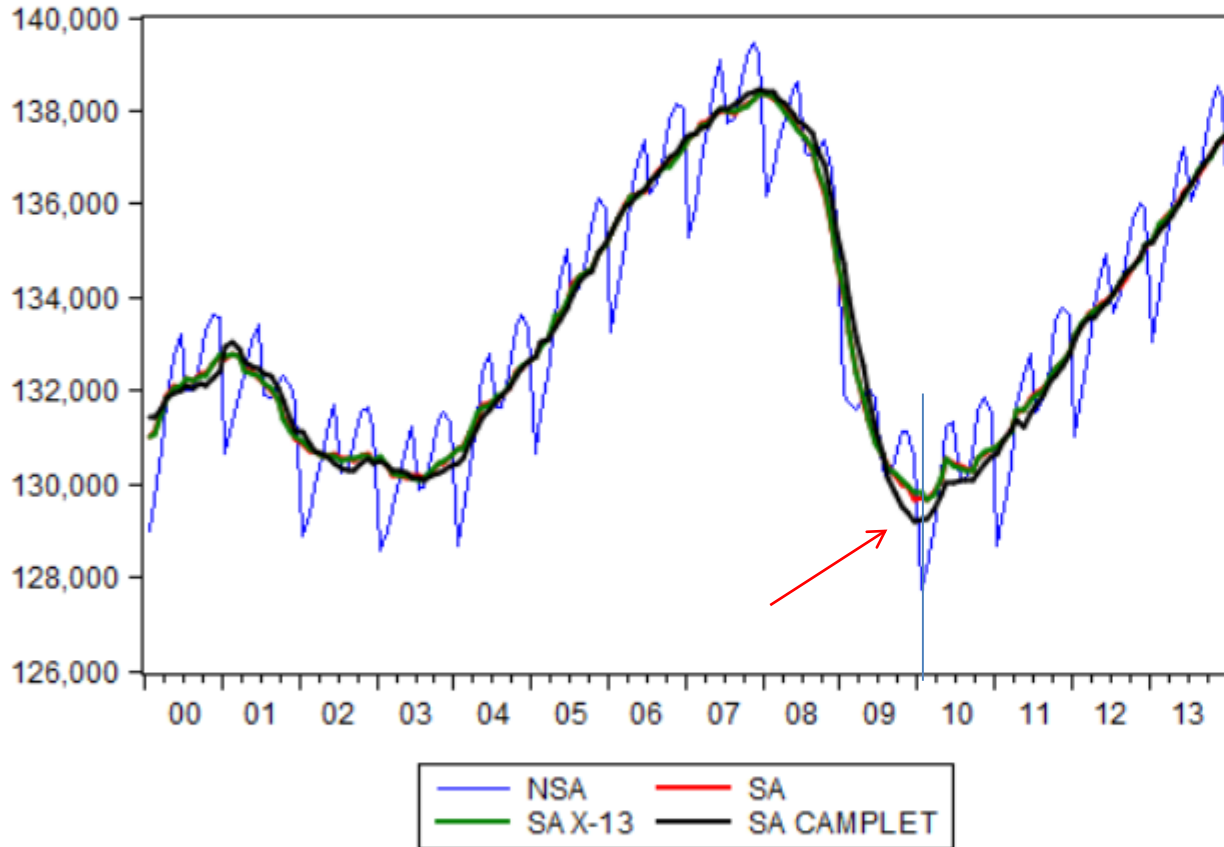

Barend Abeln, Jan P.A.M. Jacobs, Pim Ouwehand

ESMD seasonal workshop, Washington DC, April 26 2018.

Latest vintage

US non-farm payroll employment

we distinguish two components in a time series: a Seasonal component (S) and a Non Seasonal component (NS):

$$Y_t = NS_t + S_t$$

Seasonal are systematic intra-year fluctuations.
Non Seasonal fluctuations have no systematism.

Period averages of a quarterly series.

Systematism apparent if we sum and average groups of corresponding periods.

▲ period averages

★ overall average

Average NS change: Connect 2 corresponding quarters
Average NS values: Move NS change line to average.

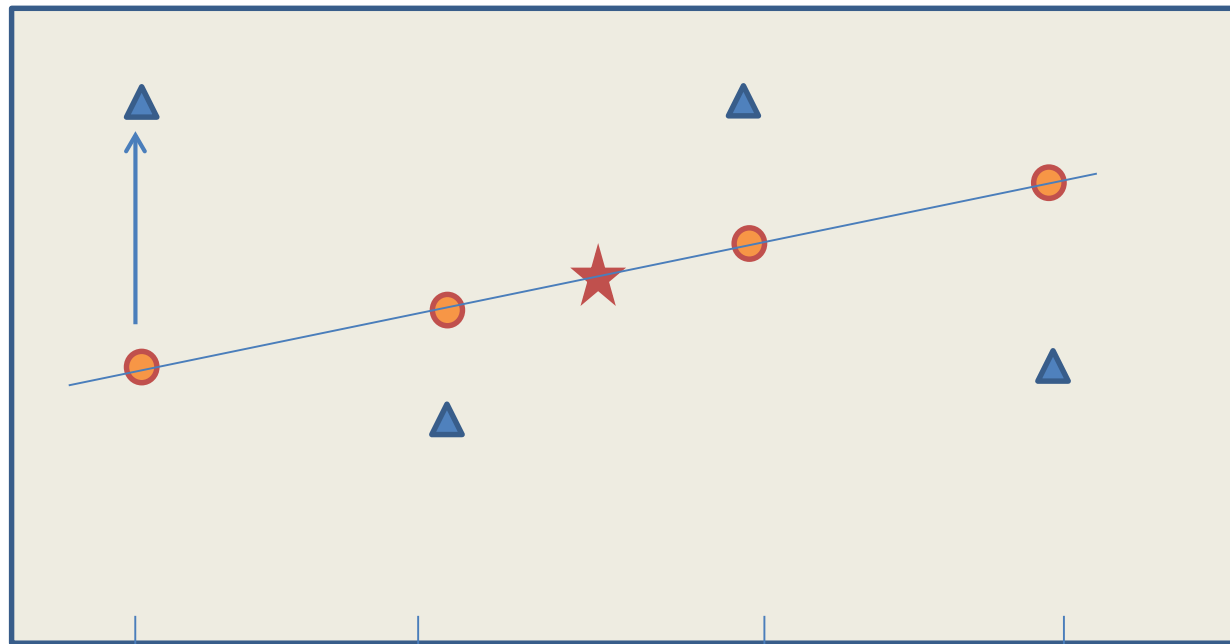

1. Gradient of average NS change

2. Average NS through overall average

NS averages make a linear progression:

● NS quarter averages

Distance from ★:

-1.5

-0.5

+0.5

+1.5

▲ Raw period averages

★ average

↑ Av. SC

1. Extend the NS to a new observation and apply the average SC:

If a next observation has this value
It can be adjusted by the Av. SC

▲ Raw period averages

● NS quarter averages

But Y_{t+1} has this value

$\rightarrow x$ } e_{t+1}

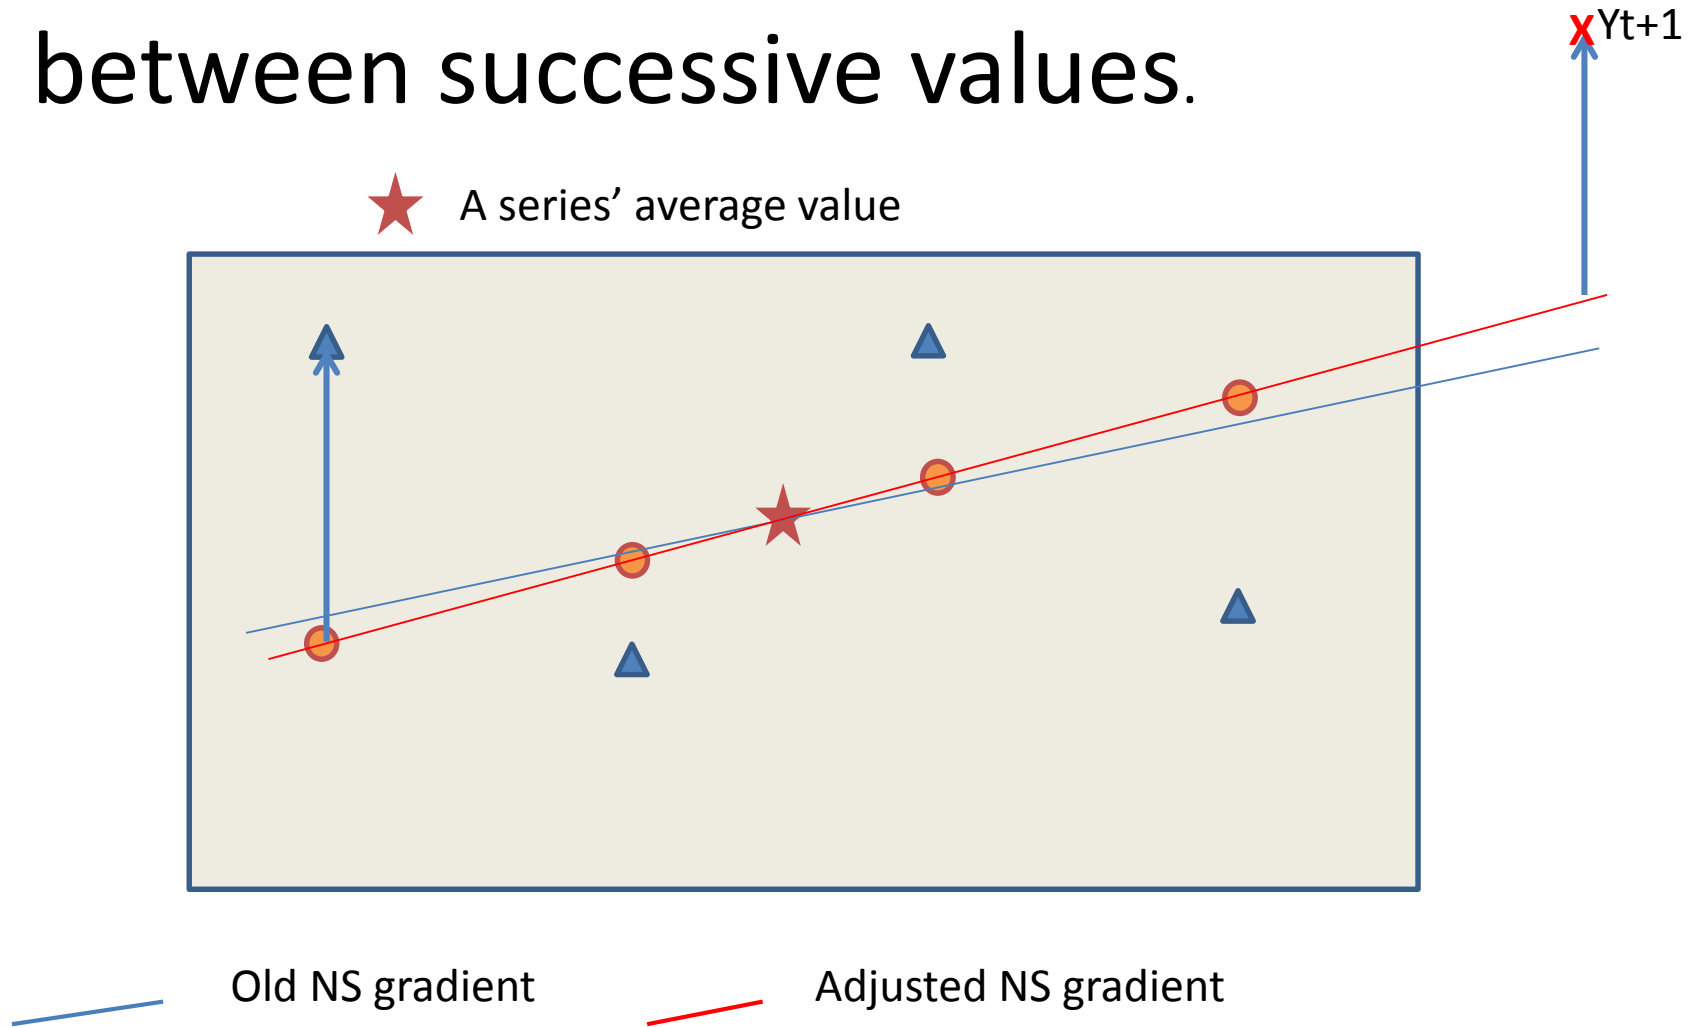

} Extrapolation error e_{t+1}

If we increment the NS gradient, all average SC change. Error e is bridged by changing NS plus changing SC. The new observation is adjusted by the updated SC.

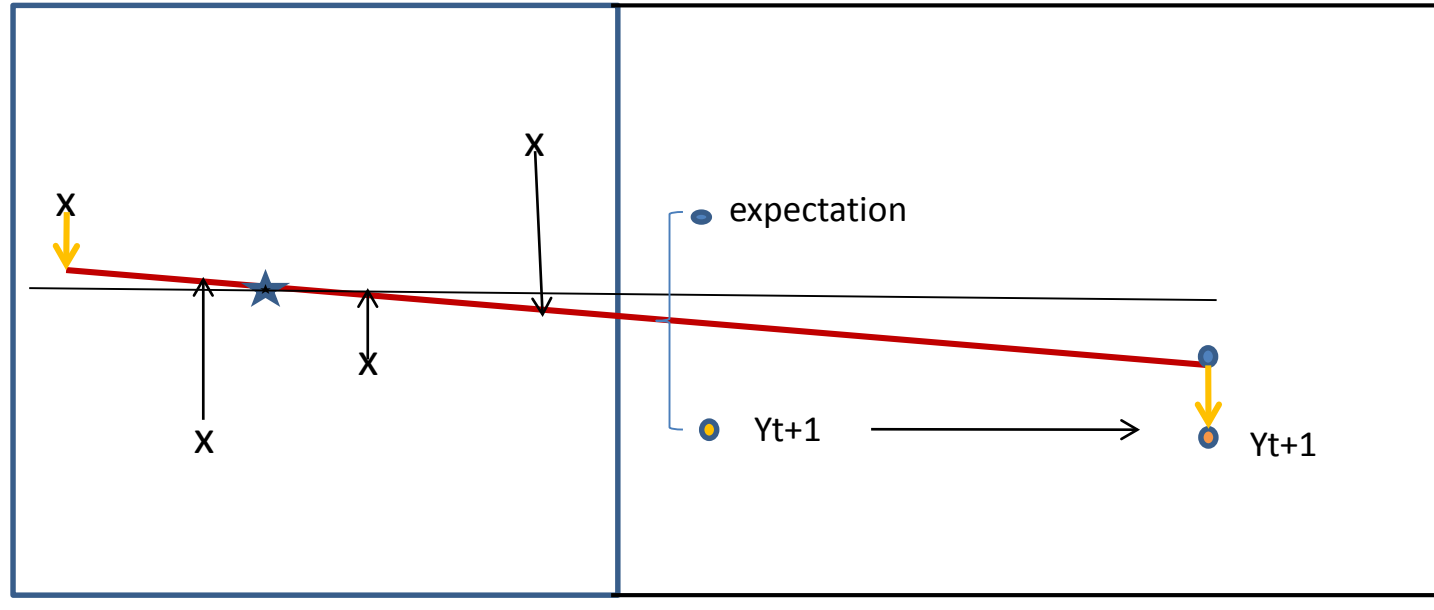

— Old NS gradient — Adjusted NS gradient
○ Y_{t+1} s.a. = NS Y_{t+1}

Camplet deseasonalizes **CHANGE** between successive values.

Change is attributed to the last observation.

If Y_{t+1} is aberrant:

With a longer adjustment length the NS gradient changes less:

Less impact on SC.

5 parameters control the adjustment length for each observation.

- CA** – Common Adjustment, the adjustment period for values that are not aberrant.
- M** – Multiplier increments the adjustment period for outliers.
- P** – Pattern shift, reduces the adjustment period to 1 year if the Seasonal Pattern shifts.
- LE** – Limit to Error is a criterion for an observation being aberrant or not.
- T** – Times: how many times must an outlier return to indicate a pattern shift.

Ahold Operating income

(an example with shifting seasonal pattern)

Source: Ahold Quarterly Bulletin (various issues)

Ahold: Change in accounting policies

As of 2008, Ahold has applied IFRS 8 "Operating segments". IFRS 8 introduces new disclosure requirements with respect to segment information. This adoption of IFRS 8 did not have an impact on Ahold's segment structure, consolidated financial results or position; however, segment results no longer include intercompany royalties.

From: Ahold Quarterly Bulletin Q1 2008

Operating income decreased from €421 million in 2007Q1 to €336 million in 2008Q1

Ahold operating income: Seasonal pattern

CAMPLET picks up change in seasonal pattern!

X13 anti-dates it to 2006.

CONCLUSIONS

1. Camplet deseasonalizes observations by comparing period change to average change.
2. No revisions,
 No impact on past decompositions
 No phase shift.
3. No pretreatment :
 variable adjustment length deals with outliers.
4. Camplet is intuitively more attractive.
